Live End-to-End Evaluation

The live end-to-end evaluation assessed the agent across ten predefined homeowner scenarios, with five repetitions per scenario, producing 50 completed trials. Each trial used the production graph and live Claude CLI calls, with scripted owner responses to make approval, rejection and clarification interactions reproducible.

The scenarios covered normal recommendation approval, refinement after rejecting a sofa, budget clarification, bathroom renovation restrictions, structural wall removal, raised flooring, owner withdrawal and a zero-budget condition. Trials were graded against their expected outcomes, including approval or parking behavior, budget validity, feedback refinement and the required compliance decision. Approved recommendations were also checked for rule violations and the inclusion of illustrative products as real purchases.

Metric	Result
Scenarios evaluated	10
Repetitions per scenario	5
Completed trials	50
Overall pass rate	**100% (50/50)**
Scenarios passing all five repetitions	**100% (10/10)**
Detected rule violations	**0**
Mean latency per completed trial	100.21 seconds
Latency range	41.29-193.26 seconds
Mean API-equivalent cost per completed trial	US$0.9275
Total API-equivalent cost for completed trials	US$46.37

All ten scenarios passed consistently across their five repetitions. The agent refined recommendations following owner feedback, handled budget constraints and produced the expected blocking, escalation or permit decisions for the tested renovation requests. It also remained unapproved when the owner did not proceed or when the total furniture budget was zero.

Execution was interrupted by Claude subscription limits, resulting in 37 recorded quota-error attempts. These attempts were subsequently retried successfully. The reported scores use the latest matching completed result for each scenario and repetition; earlier quota-error records remain in the evaluation history. Cost figures represent API-equivalent usage estimates rather than actual subscription charges.

These results demonstrate repeatable behavior within the tested scenarios. Their scope is limited to predefined journeys and scripted owner interactions; they do not establish performance across the full range of mood boards, flat configurations or open-ended homeowner conversations.
